1 Assorted Joins

- Companies: (company_id, industry, ipo_date)
- NYSE: (company_id, date, trade, quantity)

We have 20 pages of memory, and we want to join two tables Companies and NYSE on C.company_id = N.company_id. Attribute company_id is the primary key for Companies. For every tuple in Companies, assume there are 4 matching tuples in NYSE.

NYSE contains \([N] = 100\) pages, NYSE holds \(p_N = 100\) tuples per page.

Companies contains \([C] = 50\) pages, C holds \(p_C = 50\) tuples per page.

There are unclustered B+ indexes on C.company_id and N.company_id – for both indexes, assume it takes 2 I/Os to access a leaf.

(a) How many disk I/Os are needed to perform a simple nested loops join?

\[ [C] + p_C * [C] * [N] = 50 + 50 * 50 * 100 = 250050 \]

(b) How many disk I/Os are needed to perform an index nested loops join?

\[ [C] + [C] \times p_C \times (\text{cost to find matching NYSE tuples}) = 50 + 50 * 50 * (2 + 4) = 15,050 \]

(c) How many disk I/Os are needed to perform a block nested loops join?

\[
\begin{align*}
 & \text{(pages in smaller relation)} + \ceiling{\frac{\text{(pages in smaller relation)}}{\text{(pages in memory - 2)}}} \times \text{(pages in larger relation)} \\
= & \text{(pages in smaller relation)} + \ceiling{\frac{50}{18}} \times 100 = 350 \text{ I/Os}
\end{align*}
\]

(d) How many disk I/Os are needed to perform a sort merge join? This is ordinary sort-merge, not optimized sort-merge.

Sorting C: \(4 \times (50 \text{ pages}) = 200 \text{ I/Os}\)

Sorting N: \(4 \times (100 \text{ pages}) = 400 \text{ I/Os}\)

Joining: \([C] + [N] = 150 \text{ I/Os}\)

Total: \(200 + 400 + 150 = 750 \text{ I/Os}\)

(e) How many disk I/Os are needed to perform a hash join?

No recursive partitioning required.

Partitioning phase:

\[
\begin{align*}
 & \ceiling{\frac{[N]}{(B - 1)}} = 6 \text{ pages per partition for N} \\
 & \ceiling{\frac{[C]}{(B - 1)}} = 3 \text{ pages per partition for C}
\end{align*}
\]
\[(N + C) + ((B - 1) \times (6 + 3)) = 321\text{ I/Os} \]
Probing phase: \((B - 1) \times (6 + 3) = 171\text{ I/Os} \]
Total: \(321 + 171 = 492\text{ I/Os} \)

(f) Now assume the index on NYSE.company_id is clustered. What is the cost of an index nested loops join using companies as the outer relation?

\[C + C \times pC \times \text{(cost to find matching NYSE tuples)} = 50 + 50 \times 50 \times (2 + \text{ceil}(4/100)) \]
\[= 7,550\text{ I/Os} \]

2 Grace Hash Join

We have 2 tables – Catalog and Transactions.

Catalog has a total of 100 pages and 20 tuples per page. Transactions has a total of 50 pages and 50 tuples per page. Assume that the distribution among the key that we are joining on is uniform for the two tables.

(a) If we had 10 buffer pages, how many partitioning phases would we require for grace hash join? Consider which table we should build the hash table in the probing phase on.

\(T\) is smaller, need partitions of \(T\) to be at most \(B - 2 = 8\) pages.
After 1 partitioning pass, we have partitions of size 6, which is small enough.

(b) What is the I/O cost for the grace hash join then? Assume uniform partitioning.

We need 1 partitioning pass.
Partitioning phase:
\(\text{ceil}(|C|/(B - 1)) = 12\) pages per partition for \(C\)
\(\text{ceil}(|T|/(B - 1)) = 6\) pages per partition for \(T\)
\(|C| + |T| + ((B - 1) \times (12 + 6)) = 312\text{ I/Os} \)
Probing phase: \((B - 1) \times (12 + 6) = 162\text{ I/Os} \)
Total: \(312 + 162 = 474\text{ I/Os} \)

(c) For the above question, if we only had 8 buffer pages, how many number of partition phases would there be?

\(T\) is smaller, need partitions of \(T\) to be at most \(B - 2 = 6\) pages.
After 1 partitioning pass, we have partitions of size 8, which is too big. We need a second partitioning pass.

(d) What will be the I/O cost? Assume uniform partitioning.

We need 2 partitioning passes.
Partitioning phase:
\(\text{ceil}(|C|/(B - 1)) = 15\) pages per partition for \(C\)
\(\text{ceil}(|T|/(B - 1)) = 8\) pages per partition for \(T\)
\(\text{ceil}(|C|/(B - 1)) = 3\) pages per partition for second pass for \(C\)
\(\text{ceil}(|T|/(B - 1)) = 2\) pages per partition for second pass for \(T\)
\((C + T) + 2 \times ((B - 1) \times (15 + 8)) + ((B - 1) \times (B - 1) \times (3 + 2)) = 150 + 2 \times 161 + 245\)
\[= 717 \text{ I/Os}\]
Probing phase: \((B - 1) \times (B - 1) \times (3 + 2) = 245 \text{ I/Os}\)
Total: \(717 + 245 = 962 \text{ I/Os}\)
